Introduction

Applications of Autonomous Vehicles

- Autonomous vehicles are being developed by many companies for commercial and personal use
- Modeling different subsystems (such as, steering, brake, acceleration, ...) for autonomous vehicles is a challenging task
- Models for autonomous vehicle subsystems must be very accurate due to safety factors

Introduction

Problem Statement

Problem Statement

Given input-output data of different subsystems, such as steering, acceleration, brake, shift, speed, and speed control, of an autonomous (self-driving) vehicle:

- Develop mathematical and/or block diagram models of these subsystems
- Develop machine learning-based models for the major subsystems of Lexus self-driving vehicle

Introduction

Problem Statement

Problem Statement

Given input-output data of different subsystems, such as steering, acceleration, brake, shift, speed, and speed control, of an autonomous (self-driving) vehicle:

- Develop mathematical and/or block diagram models of these subsystems
- Develop machine learning-based models for the major subsystems of Lexus self-driving vehicle

Proposed Solution

- Use state-space modeling techniques based on input and output data
- Use system identification modeling techniques
- Use machine learning (neural network) based modeling techniques

Literature Review

Existing Solutions

- Use of System Identification Toolbox in MATLAB to create models from data [1]
 - Offers a variety of model choices
 - Needs a large amount of raw data to produce an accurate model
- Third order ARMAX model creates models using traditional methods of analysis [2]
 - Allows the use of traditional analysis methods to create a model
 - More room for error during calculations
- Steer-By-Wire method as a system model [3]
 - Can model systems with small non-linearities
 - Mechanical components replaced by electrical components
- Authors in [4] illustrate identification of multiple-input single-output model for maximum power point tracking of photovoltaic system.
 - Fourth order ARX model ended up giving the best fit

System Identification Preliminaries

Preliminary Work

- Documentation on MATLAB's System Identification Toolbox and tutorials
- Literature Review
- Data Collection for steering, braking and acceleration subsystems

MATLAB Example: Dealing with Multi-Variable Systems: Identification and Analysis

- Learned how to create an iddata object from a given data set
- Created a state space model and compared it to the validation data
- Tried creating submodels for some of the channels in order to try and get a better fit
- Then created a MISO model and learned how to merge the two SISO models that were created earlier

System Architecture

System Architecture

The overall system architecture of this project consists of six subsystems:

- Steering
- Acceleration
- Brake
- Shift
- Speed
- Speed control

Modeling using Neural Networks

Therefore, approximated output signal can be written as:

$$\mathbf{y} = \mathbf{W}^T \boldsymbol{\sigma}(\mathbf{x}), \quad (1)$$

where $\boldsymbol{\sigma} : \mathbb{R}^n \rightarrow \mathbb{R}^P$ with components of weight matrix \mathbf{W} shown in Fig. 10 are given by

$$\mathbf{W} = \begin{bmatrix} w^{1,1} & w^{1,2} & \dots & w^{1,m} \\ w^{2,1} & w^{2,2} & \dots & w^{2,m} \\ \vdots & \ddots & \dots & \vdots \\ w^{P,1} & w^{P,2} & \dots & w^{P,m} \end{bmatrix}.$$

Now take η data points and form the set of linear equations as:

$$\boldsymbol{\sigma}^T(\mathbf{x}_k) \mathbf{W} \approx \left(\mathbf{y}_k^{[d]} \right)^T$$

$$\boldsymbol{\sigma}^T(\mathbf{x}_{k+1}) \mathbf{W} \approx \left(\mathbf{y}_{k+1}^{[d]} \right)^T$$

⋮

$$\boldsymbol{\sigma}^T(\mathbf{x}_{k+\eta-1}) \mathbf{W} \approx \left(\mathbf{y}_{k+\eta-1}^{[d]} \right)^T$$

In compact form:

$$\Sigma \mathbf{W} \approx \mathbf{U}^{[d]}, \quad \text{with}$$

$\mathbb{R}^{\eta \times p} \ni \Sigma = [\Sigma_0, \Sigma_1, \dots, \Sigma_{\eta-1}]^T$ with $\Sigma_\kappa = \sigma^T(\mathbf{x}_{k+\kappa})$ and
 $\mathbb{R}^{\eta \times m} \ni \mathbf{U}^{[d]} = [\mathbf{U}_0, \mathbf{U}_1, \dots, \mathbf{U}_{\eta-1}]^T$ with $\mathbf{U}_\kappa = (\mathbf{y}_\kappa)^T$ for
 $\kappa = 0, 1, \dots, \eta - 1$.

Let $\Sigma \mathbf{W} \equiv \hat{\mathbf{U}}$, sum-of-squared error, δ can be written as:

$$\delta = \frac{1}{2} \|\mathbf{U}^{[d]} - \hat{\mathbf{U}}\|^2$$

Weight matrix \mathbf{W} can then be found minimizing the sum-of-square error δ defined by

$$\delta = \frac{1}{2} \|\mathbf{U}^{[d]} - \Sigma \mathbf{W}\|^2 = \frac{1}{2} \text{Tr} \left[(\mathbf{U}^{[d]} - \Sigma \mathbf{W})^T (\mathbf{U}^{[d]} - \Sigma \mathbf{W}) \right].$$

Taking the derivative of δ with respect to \mathbf{W} yields

$$\frac{\partial \delta}{\partial \mathbf{W}} = -\Sigma^T \mathbf{U}^{[d]} + \Sigma^T \Sigma \mathbf{W} \tag{2}$$

Setting $\frac{\partial \delta}{\partial \mathbf{W}}$ to zero yields

$$\mathbf{W} = (\Sigma^T \Sigma)^T \Sigma^T \mathbf{U}^{[d]}.$$

- Hidden layer to output layer weight is updated at each policy iteration $r = 0, 1, \dots$ using gradient descent approach as:

$$\begin{aligned}\mathbf{W}^{(r+1)} &= \mathbf{w}^{(r)} - \ell \frac{\partial \delta}{\partial \mathbf{W}} = \mathbf{W}^{(r)} - \ell \left(-\Sigma^T \mathbf{U}^{[d]} + \Sigma^T \Sigma \mathbf{W}^{(r)} \right) \\ &= \mathbf{w}^{(r)} - \ell \Sigma^T \left(\Sigma \mathbf{W}^{(r)} - \mathbf{U}^{[d]} \right) \quad (3)\end{aligned}$$

Modeling using Neural Networks

- Used MATLAB's Neural Network Time Series App
- All models generated using the Bayesian Regularization Algorithm
- Models trained using collected log data

Modeling Vehicle Subsystems

System Requirements

Specifications

Proposed vehicle subsystem models are expected to fulfill requirements listed below:

- Resulting plant model will consist of reasonably accurate subsystem models
- Subsystems can be used to create a HIL testbench
- Steering model can handle very small changes in steering angles
 - smooth out any non-linear discontinuities that would normally be measured by the steering motor, especially for small changes in the steering angle, depicted in 11.

By-Wire Mode

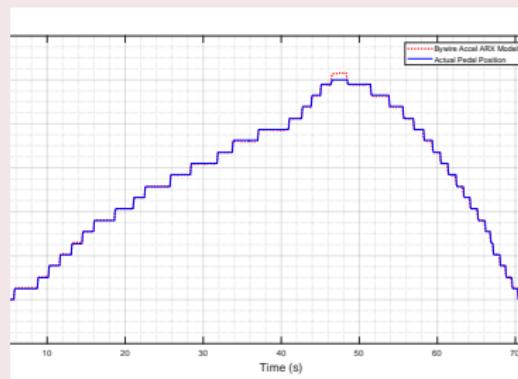

Figure 15: Output of Estimated By-Wire System Model

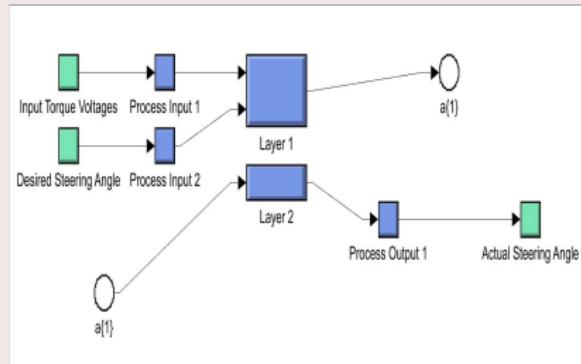

Transfer Function Modeling

Brake System Simulation

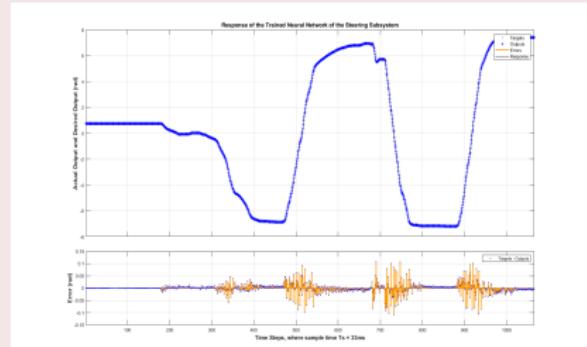

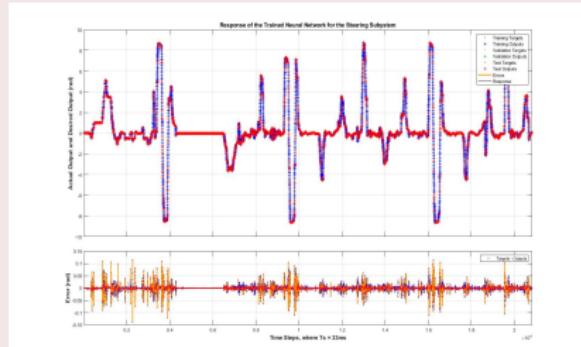

- Only manual models were considered
- There were no transfer function models that could satisfy both the best fit and error requirements

Neural Network Modeling

Steering System Simulation

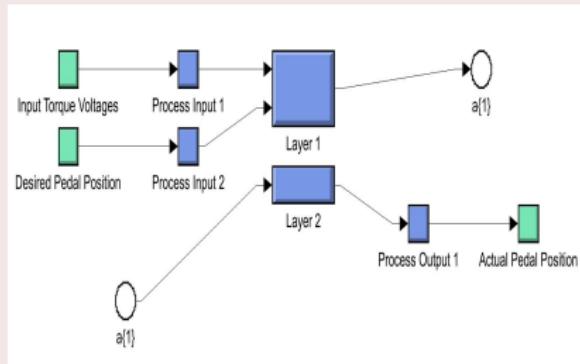

- Only a few samples are just outside of the accuracy requirements
- Transfer function model did not meet the accuracy requirements

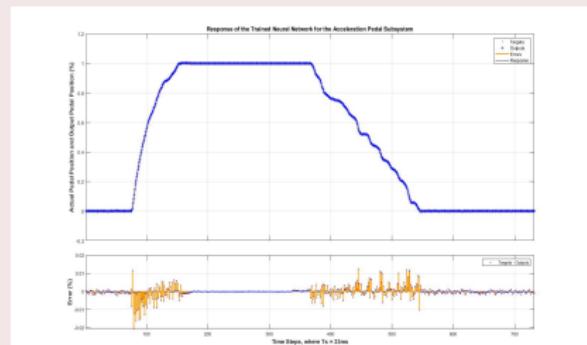

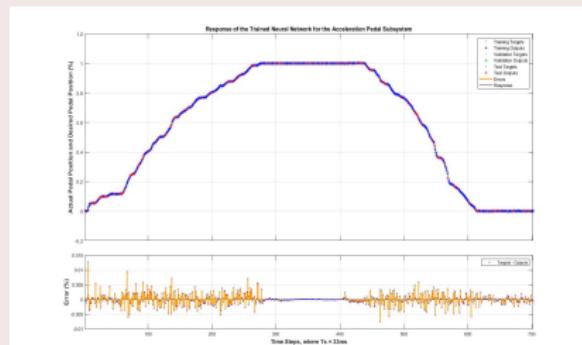

Neural Network Modeling

Acceleration System Simulation

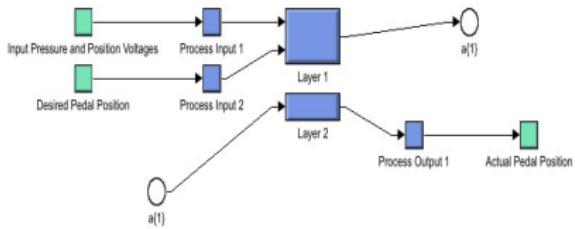

- All samples within 2% of the actual output
- Transfer function model did not have the same accuracy bounds
- Fewer concerns about connections in Simulink

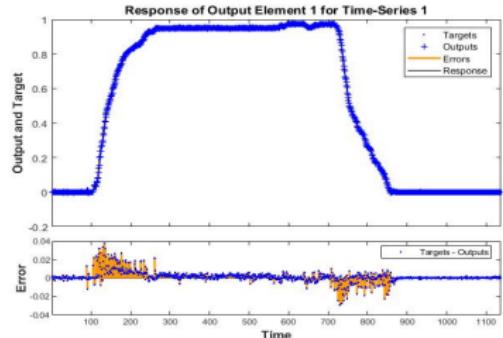

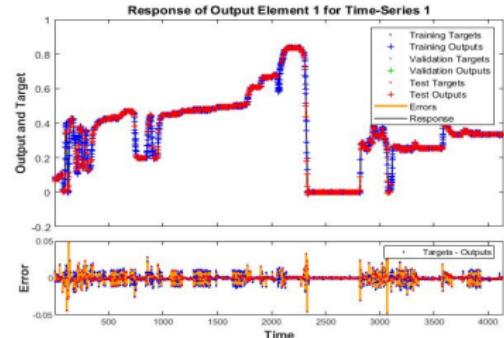

Neural Network Modeling

Brake System Simulation

- With this model, the error is kept below 5%
- Able to easily track model performance
- Provides better results than the transfer function model

Validation and Testing

Experimental Setup

Software and Hardware

- Software
 - MATLAB's System Identification Toolbox
 - MATLAB's Neural Network Time Series Toolbox
 - DSpace/Control Desk
 - Vector CANalyzer
- Hardware
 - Laptop
 - PACMod ECU
 - CANCase
 - CAN bus

Validation and Testing

Experimental Setup

Control Method

- Manual Mode
 - Vehicle is not autonomous
 - Torque voltages are sent by the vehicle ECU
- By-Wire Mode
 - Vehicle is autonomous
 - Torque voltages are sent by the PACMod ECU
 - Torque voltages sent from the vehicle ECU are discarded by open-circuiting the motors

Conclusions and Future Work

Conclusions and Challenges

- Conclusions
 - Switch from transfer function to neural network models
 - Neural network modeling worked best
- Challenges
 - Time constraints
 - Hardware constraints

Future Work

- Model shift, speed, and speed control subsystems
- Test models using Hardware-in-the-Loop
- Create new vehicle controllers
